Software Service Levels and Support

AR-SW-022 | Knowledge class: Software; internal standard and operating guide | Owner layers: 2 and 3 | Owner nodes: Software and Digital Products Division — Software Support and Deployment Team | Version: 1.0 | Date: October 2024 | Status: Approved

1. Authority, scope, and organizational placement

This document governs internal work at ArmanRayan Information Technology Company; all examples are fictional. Before use, the reader shall match its identifier and version to the project package. Ownership belongs at layer 2 to the Software and Digital Products Division and at layer 3 to the delivery team identified in the metadata. Shahab Amini coordinates the division. Under AR-ORG-002, a technical capability is not an organizational unit: the Web Development Team is the parent, while Django, Laravel, Node.js, and React are shared capabilities within it, not peer delivery teams. This document grants no authority to amend a contract or restructure the company.

2. Service scope and intake accountability

Niloufar Ahmadi is the example owner for software incident intake, prioritization, and escalation. This document establishes the internal service baseline and does not replace a signed maintenance agreement. Coverage hours, holidays, authorized requesters, and environmental access shall be explicit in the service agreement; this document promises no unsupported round-the-clock coverage. A business hour in the matrix means time inside the agreed service calendar, and a business day means a service day in that calendar. Durations without a business qualifier denote elapsed time, with the necessary coverage defined contractually. Coverage disagreements are resolved before accepting commitments with Mahsa Jalali under AR-LEG-009.

Decision and responsibility table

Priority	Response	Restoration or resolution
P1 — Complete outage	30 minutes	Temporary restoration within 4 hours
P2 — Substantial partial impact	2 hours	Resolution within 16 business hours
P3 — Low impact or ordinary request	8 business hours	Resolution within 5 business days

3. Channels and a single request record

The primary channel is the customer-agreed request system. The support email and telephone specified in the contract are supplementary channels; this document supplies no invented

reachable address or number. A complete outage requires rapid contact accompanied by creation or completion of the record. Scattered personal-chat messages do not replace official intake. Niloufar Ahmadi links duplicates to the main record and preserves the first valid receipt time. Minimum information includes impact, observation time, version, environment, authorized contact route, and evidence without confidential data. Missing information does not prevent initial response, but is recorded explicitly. Channel consolidation prevents parallel teams from making inconsistent commitments about the same incident.

4. Priority and target times

Priority 1 is complete service outage: response within 30 minutes and temporary restoration within 4 hours. Priority 2 requires response within 2 hours and resolution within 16 business hours. Priority 3 requires response within 8 business hours and resolution within 5 business days. Response means human acknowledgment with an owner and next action, not an automated message. Priority 1 temporary restoration means usable service or an accepted workaround; root-cause correction may remain separate work. Priority 2 concerns substantial impact short of total outage, while Priority 3 covers lower-impact defects or ordinary requests. A requester’s personal urgency does not replace actual service impact. Priority decisions shall record their evidence.

5. Handling lifecycle and clock control

Niloufar Ahmadi first confirms impact and scope, records priority, and identifies the next-action owner. Receipt, response, action, restoration, and customer acceptance times are retained separately. Priority changes require rationale and a timestamp without rewriting history. Waiting for a customer or supplier does not automatically stop the clock; suspension requires contractual authority, a recorded reason, and valid communication. Resolution needs test evidence and explicit remaining status. Customers shall understand temporary containment versus durable correction. An incident approaching its target is escalated to the builder and Shahab Amini for coordination before the deadline. Escalation must not be delayed merely because the full cause is not yet known.

6. Builder escalation and usable knowledge

Support escalation shall include reproduction steps, version, impact, and actions already attempted. Warehouse APIs and web architecture go to Nazanin Farahani; Laravel and Node.js to Kian Razavi; React to Hanieh Saadati; Flutter to Amin Tourani; and Windows to Roozbeh Mohseni. Routing follows AR-EXE-023 and actual capacity. Niloufar Ahmadi retains communication and record ownership; changing executors must not leave a request ownerless. A knowledge-base answer shall include symptoms, applicability, safe actions, verification, and escalation boundaries. A risky workaround or one dependent on unrestricted access is not published as general guidance without review. A resolved ticket becomes reusable knowledge only after sensitive details are removed and technical applicability is checked.

7. Azarpakhsh: obligations versus incidents

The Azarpakhsh delivery delay under AR-ISS-024 includes RAID and RAM incompatibility, Windows-client compatibility, and delayed web reporting. A project delay alone is not a Priority 1 incident; actual service impact shall be examined. Niloufar Ahmadi connects work to Roozbeh Mohseni, Nazanin Farahani, and, for components, Saeed Akbari and Farzaneh Javadi. Platform testing follows AR-HW-015, while Mahsa Jalali determines obligations or an addendum under AR-LEG-009. The revised 20 Mehr 1403 delivery remains proposed. A temporary workaround record shall not become a claim of permanent correction or contractual waiver. Support does not independently decide penalties or component charges, and technical restoration does not settle a legal dispute.

8. Target review and breach reporting procedure

For each request review, Niloufar Ahmadi first checks valid receipt time and the applicable calendar. Human response and restoration evidence are then compared with that priority’s target. If priority changed, contractual treatment is explained with history preserved; the earlier value is not deleted. A breach record states duration, customer impact, primary obstacle, and preventive action. It must not portray Priority 1 temporary restoration as root-cause resolution. For Priority 2, business hours are calculated separately from elapsed time, identifying the calendar used. Priority 3 business days are not interchangeable with calendar holidays. Disputed interpretation goes to Shahab Amini and, for obligations, Mahsa Jalali. Reporting serves transparency and improvement rather than manipulation of indicators or retrospective rewriting of commitments.

9. Incident closure and knowledge publication

Before closure, support shall record restoration tests, outcome communication, and remaining work. If the customer has not replied, follow-up uses the contractual process; silence alone is not definitive acceptance. A knowledge article shall state applicability so a workaround for one version is not recommended for every version. Niloufar Ahmadi reviews clarity and the builder reviews technical accuracy. Customer data, passwords, and access details are removed. The article shall identify symptoms requiring a stop and escalation. Publishing knowledge does not discharge an open obligation, and root-cause work remains tracked until its outcome is observable. The closure record and reusable article remain linked but serve different purposes.

10. Input control and decision procedure

The control procedure starts with a recorded request. The executor shall describe the problem, intended user, environmental constraint, expected output, and acceptance criterion in a traceable statement. Dependencies shall then be distinguished from assumptions, with required evidence identified for each assumption. Work with insufficient inputs returns for clarification; customer silence does not constitute approval. A decision record shall state the alternative considered, selection rationale, effects on other work, and the person responsible for follow-up.

Where scope or ownership changes, Mahsa Jalali performs the legal review under AR-LEG-009. A verbal promise does not replace a recorded decision.

11. Evidence, versioning, and citation

Every output shall link to its request, reproducible version, and review result. Minutes, a test screenshot, or a design file without environmental context and a date are not complete evidence. Knowledge records shall separate direct observation from interpretation and recommendation. A definitive claim is permitted only when its evidence is attached or accessible in the controlled repository. Evidence retention must not disclose confidential customer information; demonstration data shall replace operational data. Citations shall include this document identifier and the section title so retrieval in the ArmanRayan Organizational Knowledge Library at layer 4 reaches a clear, independently understandable passage.

12. Cross-team handoff and acceptance control

The delivering team shall prepare a package describing the output, known limitations, open dependencies, and validation method. The receiving team records acceptance, conditional acceptance, or return for correction. Conditional acceptance shall identify the condition, its owner, and evidence needed to close it; it is not equivalent to completion. A technical disagreement is first examined within the relevant team and goes to Shahab Amini for coordination when it affects another team. Disagreement over customer obligations goes to the Legal and Contracts Unit. Transfer to support does not remove the builder’s responsibility to correct a known defect.

13. Exceptions, stop conditions, and executor routing

If an output cannot be tested, required access is unavailable, or data loss is plausible, the executor shall stop the risky portion and record the reason. Work may resume only after an alternative control and responsibility for risk acceptance are explicit. An exception shall be bounded, reviewable, and project-specific; it does not automatically become general policy. AR-EXE-023 is the reference for authorized executor domains and available capacity; expertise does not imply unlimited availability. Multi-part problems shall be divided into independent subproblems, with relevant knowledge and a proposed executor recorded for each under the AR-ISS-024 model.

14. Lessons learned and controlled revision

After a handoff or incident, the work owner shall write a concise account of the original problem, action taken, observable outcome, and remaining limitation. The account must be understandable to a colleague who did not attend the discussion. Unnecessary identifying information shall be removed and ambiguous terms defined. The owning team checks technical accuracy and relevance before the citable version enters the ArmanRayan Organizational Knowledge Library. Repeated defects indicate a need to improve the method, not necessarily

individual fault. A proposed revision shall identify the affected clause, rationale, and effect on dependent documents; the approved text shall never be replaced without traceability.

Final control and definition of done

Done control	Acceptance evidence
Clear input	Recorded request, scope, and acceptance criteria
Independent review	Reviewer identity and correction outcome retained
Validation	Normal, failure, and permission scenarios checked
Delivery package	Version, limitations, instructions, and rollback clear
Acceptance and knowledge	Handoff outcome and lesson linked to request
